

Appendix IX

Assessment Form of Senior Thesis

Supervisor's comments (more than 50 EN words):

The thesis addresses an important problem: whether memory-augmented LLM agents can support longitudinal clinical reasoning over real-world EHR histories. The student demonstrates strong independence in formulating the research question, designing a clear three-tier memory architecture from MIMIC-IV dataset and constructing the long-horizon reasoning task with systematic ablation experiments across multiple models and memory strategies. The work is technically solid, and its empirical results are meaningful, indicating that current LLMs, RAG strategies and memory components do not yet reliably improve clinical decision-making beyond immediate context. The thesis also shows good awareness of benchmark validity and technical limitations. Overall, this is a good senior thesis with clear research value.
